In our original sample (Bowers, Holmes & Rohm, 2010), the resulting 289 cases located were mostly in the northern hemisphere (n = 271). Most previous reports, on the findings individual or almost entirely male distribution (96%), and mass murders were often preceded by significant status threats or threats to psychological integrity, such as unemployment, relationship problems, or similar problems. Psychological status was often difficult to judge from newspaper reports, but anger, depressive difficulties, and psychosis appeared to be common in mass murderers.

We reviewed national and international press reports of mass murder incidents between 1996 and 2013. The information was gathered from a variety of reliable media sources. In addition, we focused on psychogenic mass murders, rather than mass murders undertaken by militia, quasi-militia, or internet-based groups. Although mass murders are relatively frequent in China, this area was not sampled, as killings based on war or religious ideals were beyond the scope of this study. In our previous reports, our findings indicated that mass murders are commonly motivated by familial, psychogenic and instrumental factors. Legislation to restrict access to firearms constitutes a central focus of this study. In this century, Australia has had only limited incidents of mass murder in this century with only two incidents in this century, only one of which was actually a mass murderers. Unfortunately, he appears to be right, even in this century.

Mass murders in the International Context: The Impact of Weapon Control
